Keywords

Outcome assessment (Healthcare); Psychometrics; Palliative Care; Child; Quality of Life; Pediatrics

What is already known about this topic?

- The use of outcome assessment tools are important to measure quality and effectiveness of care.
- The population of children requiring paediatric palliative care services is diverse.
- There are no outcome assessment tools validated specifically for use within paediatric palliative care

What this paper adds?

- This is the first review to systematically identify existing health-related quality of life outcome measures for use in paediatric palliative care.
- The paper finds that there is currently no 'ideal' outcome assessment tool for use in paediatric palliative care.

Implications for practice, theory or policy

- A selection of both outcome and experience measures for use within this population may be useful.
- In order to measure what is important to the individual child and family it may be better to allow them to choose their own goals for care and treatment.

ABSTRACT

Background: The number of children worldwide requiring palliative care services is increasing due to advances in medical care and technology. The use of outcome measures is important to improve the quality and effectiveness of care.

Aim: To systematically identify health related quality of life (HRQOL) outcome measures that could be used in paediatric palliative care (PPC) and examine their feasibility of use and psychometric properties.

Design: A systematic literature review and analysis of psychometric properties.

Data sources: PsychInfo, Medline and EMBASE were searched from 1 January 1990 to 10 December 2014. Hand searches of the reference list of included studies and relevant reviews were also performed.

Results: From 3460 articles, 125 papers were selected for full text assessment. 41 articles met the eligibility criteria and examined the psychometric properties of 22 HRQOL measures. Evidence was limited as at least half of the information on psychometric properties per instrument was missing. Measurement error was not analysed in any of the included articles and responsiveness was only analysed in one study. The methodological quality of included studies varied greatly.

Conclusion: There is currently no 'ideal' outcome assessment measure for use in PPC. The domains of generic HRQOL measures are not relevant to children receiving palliative care and some domains within disease-specific measures are only relevant for that specific population. Potential solutions include adapting an existing measure or developing more individualized patient centred outcome assessment measures. Either way, it is important to continue work on outcome measurement in this field.

Background

Palliative care for children begins at diagnosis and encompasses children with a variety of life limiting and life threatening conditions. Life limiting conditions are diseases where there is no reasonable hope of cure and that will ultimately be fatal¹. Life threatening conditions are those where curative treatment may be possible but can fail, for example cancer. Worldwide, more children are living longer with such conditions due to advances in medical care. Paediatric palliative care (PPC) is about helping children and their families deal with their medical condition, while enabling them to live life to the fullest.² Palliative care for children and young people (CYP) is an active and total approach to care, and begins at the point of diagnosis, throughout the child's life, death and beyond.³ The scope of paediatric palliative care is broad and PPC services care for children and young people with a wide variety of illnesses, many of which are extremely rare.^{3,4} Children can be receiving care from these services for many years and therefore it is imperative to ensure that they are supported to live life to their fullest potential.

Health related quality of life (HRQOL) has been described as a subjective, multidimensional and dynamic construct that comprises physical, psychological and social functioning.⁵ HRQOL measurement instruments must consist of physical, social and mental health dimensions as delineated by the World Health Organisation (WHO).⁶ Given that one of the goals of PPC is to improve HRQOL, service providers, researchers, fundraisers and policy makers will want to measure HRQOL and determine the effectiveness of services in achieving this.

There are no paediatric HRQOL measures that have been successfully validated for use within PPC. One study did attempt to validate the well-used Pediatric Quality of Life 4.0 measure in children with a variety of life-limiting conditions. However, the study found that the instrument did not have valid psychometric properties for use within this population.⁷ Therefore, within PPC two possibilities exist; devising a completely new HRQOL instrument, or revising and validating an existing one. A review of existing HRQOL measures is essential prior to deciding which course of action to take.

The aim of this systematic literature review is to examine the measurement properties

of existing HRQOL instruments for use in those up to 18 years old. It will also assess the feasibility of the measures being used in the CYP palliative care population in terms of completion time, response options, recall period, format, domains and whether the measure is parent, professional or self-completed.

Methods

This systematic literature review was performed in accordance with Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines.⁸

Identification of Studies

PsychInfo, Medline and Embase were searched from 1 January 1990 to 10 December 2014. Experts in the field of were asked to suggest any further measures. The search terms used included keywords such as child, adolescent and teenager in combination with terms used to find studies on measurement properties of health related quality of life measures.^{9,10} Language restriction to the English language was applied due to practical constraints within the research team. Reference lists of included articles were also searched for further publications. Box 1 shows the search strategy used.

Inclusion/Exclusion Criteria

A study was included if it met the following inclusion criteria:

- Full text article
- Written in the English language
- Examining one or more measurement properties of an instrument that measured physical, mental and social aspects of HRQOL as delineated by WHO⁶
- The study population were under 18 years old
- The measure was generic or disease specific
- Disease specific instruments had to assess HRQOL in an illness considered to be life-limiting or life-threatening^{3,4}
- Studies of generic measures were included only if some or all of the population in the study had a life-limiting illness
- Included measures could be completed by the CYP, parent or clinician

Study Selection

The results of the search were thoroughly checked and full manuscripts of all studies whose title/abstract seemed to meet the selection criteria were retrieved. Independent reviewers (LC and GL) examined these full text articles and made the final decision as to whether they were included.

Data extraction

The methodological quality of included studies was rated using the Consensus based Standards for the selection of health Measurement Instruments (COSMIN) checklist.¹¹ This checklist contains nine boxes, each dealing with one measurement property. There are 5-18 items per box (98 items in total) that can be used to assess whether a study on a specific measurement property meets the standard for good methodological quality. The checklist evaluates the following measurement properties: internal consistency, reliability, measurement error, content validity, construct validity (structural validity, hypothesis testing, cross-cultural validity), criterion validity and responsiveness. There are three additional boxes: one to assess the methodological quality of studies on interpretability, one to assess the generalisability of results and one that includes extra methodological standards for studies that use item-response theory (12 boxes in total). Each item is scored on a 4-

point rating scale (poor, fair, good, excellent).¹² An overall score for the methodological quality of a study is determined for each measurement property separately, by taking the lowest rating of any item in a box (worst score counts).¹¹

Box 2 gives definitions of these measurement properties.

Box 2. Definitions of measurement properties

Reliability

This term is used twice – as a term for the domain and also as the term for the measurement property.^{13,14} Defined as the degree to which measurement is free from measurement error. Includes internal consistency, reliability (test-retest, inter-rater, intra-rater) and measurement error.^{12, 13, 15}

Validity

The degree to which a tool measures the construct it claims to measure. Includes content validity, criterion validity and construct validity.^{13,15}

Responsiveness

The ability of an instrument to detect change over time in the construct being measured.¹⁶

Interpretability

The degree to which qualitative meaning can be assigned to the quantitative scores or change in scores of an instrument. This is an important property of an instrument but not a measurement property.¹³

Synthesis of results

To summarise the evidence of measurement properties of each included instrument, the results were combined. The number and methodological quality of the studies were taken in to account, along with the consistency of results. A method similar to that proposed by the Cochrane Back Review Group was used (Table 1).¹⁷

The overall rating of each measurement property is ‘positive’, ‘negative’ or ‘indeterminate’, accompanied by levels of evidence. These criteria were originally meant for systematic reviews of clinical trials but have been used in reviews on measurement properties.¹² To assess whether results of measurement properties were positive, negative, or indeterminate, criteria based on Terwee et al were used (Table 2).¹⁸

This assessment of measurement properties was then looked at alongside the feasibility of each measure being used in PPC in terms of completion time, response options, recall period, format and domains.

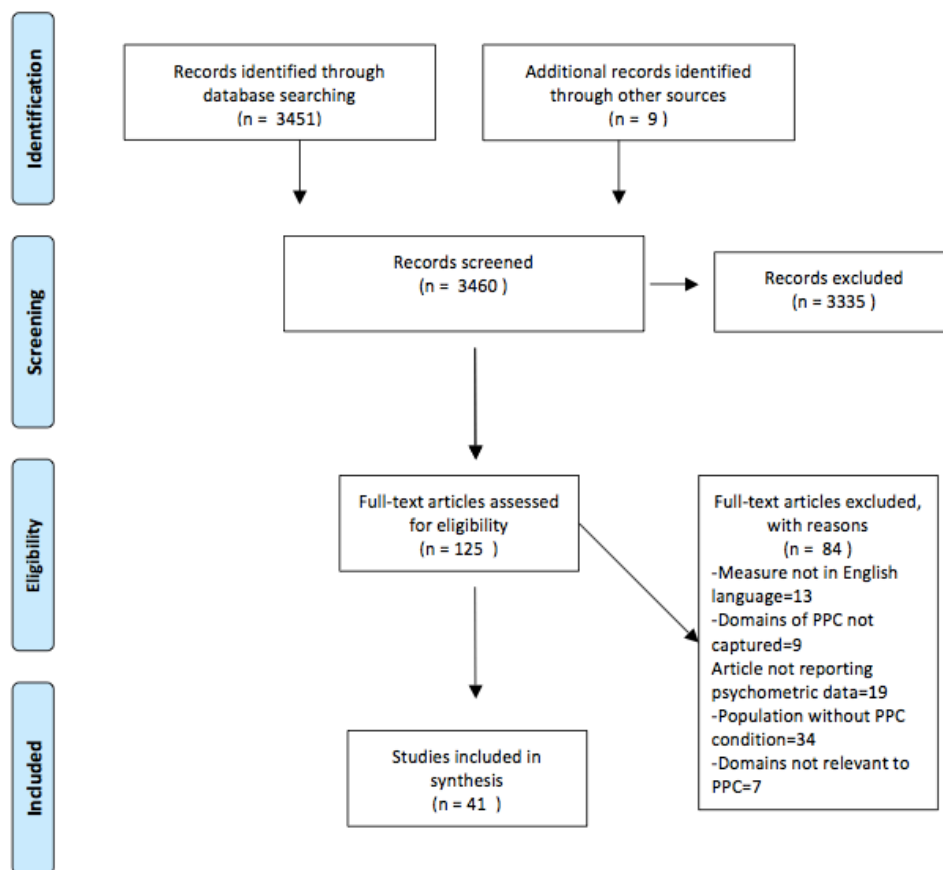

Research ethics committee/IRB approvals were not required as this was a systematic review of pre-existing evidence

Results

Paper selection

Three thousand four hundred and fifty one articles were found using the search strategy and a further nine were found via reference searching. One hundred and twenty five of these were selected for full text review based on title and abstract. Forty one were selected to be included in the review. Figure 1 shows a flow chart of the article selection process and table 3 shows the general characteristics of included studies.

Figure 1. PRISMA flow chart

From Moher et al.⁸

Summary of results

The 41 articles included evaluated 22 health related quality of life measures for use with children aged 0-18 years old. Two papers discussed the results from the same study so were only analysed once.^{19,20} All included measures were originally developed to be completed in paper format. Five of the included measures were generic and 17 were disease specific. Of the disease specific measures, three are for use with children with cardiac disease, three for cerebral palsy, six for cancer, one for brain tumours, three for epilepsy and one for neuromuscular disease. Four measures are child completed, four parent completed, thirteen have both parent and child forms and one measure had both child and clinician forms. Completion time ranged from two to 25 minutes, with the number of items ranging from six to 87. Recall time ranged from the current moment to one month. Table 3 shows a summary of the included studies, where data is missing it is because it was not available.

None of the studies included analysed measurement error or cross-cultural validity. One study reported on responsiveness and one on criterion validity³¹. The COSMIN panel define criterion validity as 'the degree to which the scores of an instrument are an adequate reflection of a gold standard'.¹⁶ As outcome measures focus on perceptions that may be subjective, they usually lack a gold standard. The only exception to this would be if a shorter version of a measure was developed from an already validated longer one, where the longer version could be considered to be the gold standard. Therefore, the results of this analysis of criterion validity have not been included here.

The methodological quality of included studies is shown in Table 4 and ranged from poor to excellent. Table 5 shows the synthesis of results per outcome measure with levels of evidence of quality. This ranged from strong to unknown.

Internal consistency was tested in 34 of the included studies. However 40% of these lacked a check of the uni-dimensionality of the scale, leading to a score of poor for methodological quality.⁵⁹

Test-retest reliability testing was carried out in 14 of the studies. 38% of studies had a sample size of at least 100 which is needed for an excellent quality score¹¹. Only one

study described how missing items were handled. If not handled appropriately this could lead to over or under estimation of reliability.

Content validity testing was carried out in 13 of the included studies. The main flaws in the methodology of content validity testing were inclusion of only small numbers in focus groups, pilot studies and cognitive testing, and not involving children, parents and professionals in the process. Ideally, all should be included to make sure the items are relevant and ensure no important items are missing.

Structural validity can be assessed by factor analysis or item response theory (IRT) tests for dimensionality.¹² Structural validity was assessed in 14 of the studies and generally there was appropriate use of confirmatory or exploratory factor analysis. In order to carry out structural validity testing a sample size of 5-7 times the number of items (and greater than 100) is recommended.¹¹ This was achieved in 93% of the studies. Lack of description of missing items and how they were handled let down 64% of the studies.

Only one study analysed responsiveness.⁵⁸ No correlations between change scores were calculated in the included study, a paired t-test was carried out instead thus the methodology for this was scored as poor. Sample size was also inadequate and there was no description of how missing items were handled.

Discussion

Main findings

To the authors' knowledge, this is the first systematic review of outcome measures that could potentially be used in paediatric palliative care. The aim of this review was to examine the feasibility of use of measures, as well as the methodological quality of analysis of measurement properties of included studies. The review identified 22 measures, five generic and 17 disease specific, that could potentially be useful. The disease specific measures included those for use in children with cardiac disease,^{25,38,39,40,51} cerebral palsy,^{26,27,52,} cancer,^{34,35,36,37,41,50,58} brain tumours,⁴⁹ epilepsy^{31,32,56} and neuromuscular disease.^{53,54,55} All measures were initially developed in the English language. None of the measures were developed for use in CYPs receiving palliative care. All were developed to be completed in paper format, predominantly by the CYP and/or their parent.

The PedsQL™ Generic Core Scale was the most widely analysed in terms of its measurement properties. It is unique because it contains a generic core scale and various disease specific modules that can be administered alongside the core scale.

Quality of assessment of measurement properties

None of the studies on measurement properties in this review achieved a score of fair methodological quality or higher in all characteristics. Most of the studies show positive results (except parent test-retest reliability in two studies and hypothesis testing in one, see table 5). Evidence is mainly limited and at least half the information on measurement properties per questionnaire is missing. The methodological quality of the included studies varied greatly and therefore results should be treated cautiously.

Internal consistency, reliability, content validity and hypothesis testing were widely assessed in the papers. Only one study analysed responsiveness (Watson et al).⁵⁸ It is imperative that any measure used to assess HRQOL is responsive to change, particularly in paediatric palliative care, where a child's condition can change frequently and sometimes rapidly. Measurement error was not tested for in any of the

included studies. With the same data, both reliability and measurement error can be calculated.¹² 14 of the 22 included studies assessed reliability, thereby measurement error could easily have been reported on.

Feasibility of Use of Included Measures

In adult palliative care there are concerns regarding the use and relevance of outcome measures.⁶⁰ These concerns include the method of administration and whether the patient, carer or professional completes the measure.⁶⁰ These concerns are probably just as applicable to PPC. Many children requiring palliative care services are non-verbal or too unwell to self-complete the tools and thereby rely on the reports of their carers and/or professionals. The method of administration of a measure is also important. Different modes of administration may be appropriate depending on the type and stage of a CYPs illness. The PedsQLTM is the only measure included in this review that has been validated across different modes of administration.⁴⁸ Multi-group confirmatory factor analysis was performed showing strong factorial invariance across three modes of administration groups (mail, in-person and telephone survey). With widespread mobile technology now available, new ways of collecting data, such as online or via an app should be considered as these may be more acceptable to CYPs and their carers, as well as being easier to access.

Within PPC, as in adult palliative care, there is a debate as to who should complete outcome measures. Most children with life limiting and life threatening illnesses are cared for at home by their parents, so a clinician completed measure is not always ideal. HRQOL is generally understood as a latent, not directly observable construct, and contains the perceptions and evaluation of one's life from the subjective view of the individual, as well as the individual's subjective well-being and affective mood.⁶¹ Wherever possible, the child's self-report of HRQOL should be sought. Within this population some children will be too young or too unwell to complete a measure and a parent/proxy completed measure will need to be used. Nineteen of the 22 measures included in this review contain parent reports. Of those studies that looked at correlation between child and parent scores three found moderate correlation between parent and child scores.^{37,38,49} One study showed poor correlation in the psychological and emotional subscales.⁵² These results support those of previous

studies that show a higher correlation for observable constructs, such as physical aspects, and a lower correlation for non-observable constructs such as emotional problems between parents and children.⁶²

Recall period in the included studies ranged from the current moment to 1 month. Research has shown that children as young as 8 years can use a 4 week recall period with accuracy.⁶³ However, HRQOL measures with shorter recall periods are likely to elicit more accurate responses.⁶⁴ Most of the disease specific measures had shorter recall periods, which is more appropriate as there can be variation in symptoms over a longer period in many cases. Children with palliative care needs often have frequently changing symptoms which can affect their HRQOL so a measure with a shorter recall period may be more appropriate.

There were a variety of response options used in the included measures. The most common method was a Likert scale and response options ranged from 3-9 points. It has been recommended that fewer responses should be employed for younger children as they tend to choose responses at the extremes.⁶³ There is also little evidence showing that young children can effectively respond to Likert scales.⁶⁴ The completion time (when reported) for measures was between 2 and 25 minutes. Shorter measures are preferable in PPC as children will fatigue easily. Shorter parent completed measures are also preferable as parents will already have the burden of caring for their sick child.

HRQOL instruments may be either generic or disease specific.⁷ Generic measures are useful for comparing general quality of life across different populations. These measures are used with healthy children so are more likely to have been validated based on large samples but may lack sensitivity in sick children and young people. Disease specific quality of life instruments, on the other hand, are used to compare quality of life within a given condition. Disease specific measures are assumed to be more sensitive to the implications of different illnesses and may be more appropriate for evaluating interventions or different treatments within CYPs with the same illness.⁶² The drawback of this is that it is not possible to compare HRQOL across groups of CYPs with different illnesses, which is essential for a discipline as wide and

varied as PPC. The measures included in this study contain varying numbers of domains but all covered the constructs of HRQOL (physical, emotional and social). Some of the domains included in the generic HRQOL measures may not be relevant for the PPC population. For example, domains such as school environment may be irrelevant for a child near the end of life. One of the included studies aimed to validate the PedsQL™ in children with life-limiting illnesses.⁷ Confirmatory factor analysis did not support the construct validity of the PedsQL™ in this group of children, implying that the hypothesized HRQOL structures between children with life-limiting illnesses and other populations may be different. Most of the generic measures included in this review do not capture the impact of life-limiting illness on daily functioning and well-being.

Implications for research

As discussed above, it is questionable whether any of the include generic measure, such as the PedsQL™ and Child Health Questionnaire would be valid in the PPC population without adaptation, due to concerns regarding construct validity. The Memorial Symptom Assessment Scales for children could potentially be useful in PPC.^{34,35} Although they capture many of the domains of PCC, they would need testing for validity and reliability in the population. It is unlikely that without adaptation, they would be useful in a non-cancer population as there is a question about hair-loss, which is unique to this group of children. The methodological quality of studies on the MSAS was fair throughout. Other disease specific measures included in this review may be useful in PPC. For example, the PedsQL™ Neuromuscular module was designed for use in children with spinal muscular atrophy and muscular dystrophy which are both life-limiting conditions.^{53,54,57} However, within the three studies included in this review, the majority of assessment of its psychometric properties was scored as fair or poor. It is unlikely that any of the included measures would have acceptable measurement properties in the entire range of children receiving PPC services, as the population is so diverse.

None of the measures included in this review meet all the requirements for use in the PPC population. The generic measures do not capture the full impact of living with a life-limiting illness and often have recall periods that could be considered too long in a child whose condition may be changing frequently. The disease specific measures

contain domains that are only relevant to CYPs with specific illnesses so could not be used to compare children with different conditions. One potential solution to this is to revise an existing instrument. An alternative is to develop a completely new measure. It is questionable whether by using either method it will be possible to develop a HRQOL outcome measure for a population as diverse as PPC. Children have many different types of illness, some of which are extremely rare and each illness comes with its own set of physical, psychological and emotional needs. All items in a measure may not be equally useful for children with different life-limiting conditions. Findings from other studies have suggested that static models (all items are administered to all subjects) will increase measurement error and decrease precision.⁷ The use of item response theory (IRT) along with computerized adaptive testing (CAT) may better assess HRQOL for this population.⁷ Alternatively, using individualized measurement tools rather than standardized ones may be a solution.⁷ The Schedule for the Evaluation of Individual Quality of Life (SEIQoL) has been shown to be valid and reliable in a population of terminally ill adult cancer patients.⁶⁵

Two relatively new concepts in healthcare, patients reported experience measures (PREMs) and patient centered outcome measures (PCOMS) may also be beneficial to CYPs and their families receiving palliative care services, but more research in this area is required. PCOMs involve putting patients and their families/carers at the heart of deciding which goals are most valuable for an individual, rather than clinicians deciding what is best.⁶⁶ PREMs measure patient experience with the goal of improving services. It is desirable to combine measures of experience with measures of outcome to obtain a rounded view of the quality of care.⁶⁷

Strengths and Limitations

This review has several strengths. First of all, this is the first review the authors are aware of which examines the measurement properties and feasibility of using already developed outcome measures in the paediatric palliative care population. The review was comprehensive, the search strategy found more than 3000 articles for potential inclusion and over 40 papers were systematically appraised and compared.

This review also has several limitations. Firstly, it is never possible to be sure that all relevant studies have been identified. The COSMIN check list is based on expert

group opinion. The inter-rater agreement of the COSMIN checklist is reported adequate. The inter-rater reliability for many COSMIN items is poor, which has been suggested to be due to interpretation of checklist items.⁶⁸ Selected articles were restricted to English language. Finally, it was sometimes not clear if certain criteria on the COSMIN checklist were not performed or not reported on. Therefore it was not possible to distinguish between poor reporting and poor quality.

Conclusion

Although there is no 'ideal' HRQOL measure for use in paediatric palliative care at the moment it is important to continue developing and researching measures in this area.

Outcome measurement in PPC is rarely carried out and as of yet there are no specific HRQOL measures for use in this population. In light of new developments in the field of PREMS and PCOMs it may be desirable to develop a combination of measures that are able to measure outcomes that are important to the individual child and family, as well as measuring their satisfaction of the experience of the services that deliver care. The purpose of measuring quality of life and outcomes in CYPs receiving PPC is potentially fourfold; to improve clinical care, to audit and evaluate services, for research purposes and to inform commissioners and secure funding.⁶⁰

Table 1. Levels of Evidence for Overall Quality of Measurement Property

Level	Rating	Criteria
Strong	+++ or ---	Consistent findings in multiple studies of good methodological quality OR in one study of excellent methodological quality
Moderate	++ or --	Consistent findings in multiple studies of fair methodological quality OR in one study of good methodological quality
Limited	+ or -	One study of fair methodological quality
Conflicting	±	Conflicting findings
Unknown	?	Only studies of poor methodological quality

+ positive results - negative results

Source: Tulder et al ¹⁷

Table 2. Quality Criteria for Measurement Properties

Property	Rating	Quality Criteria
Reliability		
Internal Consistency	+	(Sub)scale unidimensional AND Cronbach's alpha(s) ≥ 0.70
	?	Dimensionality not known OR Cronbach's alpha not determined
	-	(Sub)scale not unidimensional OR Cronbach's alpha < 0.7
Measurement Error	+	MIC > SDC OR MIC outside the LOA
	?	MIC not defined
	-	MIC \leq SDC OR MIC equals or inside LOA
Reliability	+	ICC/weighted kappa ≥ 0.70 OR Pearson's r ≥ 0.80
	?	Neither ICC/weighted kappa, nor Pearson's r determined
	-	ICC/weighted kappa < 0.70 OR Pearson's r < 0.80
Validity		
Content validity	+	The target population considers all items in a questionnaire to be relevant AND considers the questionnaire to be complete
	?	No target population involvement
	-	The target population considers items in a questionnaire to be irrelevant OR considers the questionnaire to be incomplete
Construct validity		
Structural validity	+	Factors should explain at least 50% of the variance
	?	Explained variance not mentioned
	-	Factors explain $< 50\%$ of the variance
Hypothesis testing	+	(Correlation with an instrument measuring the same construct ≥ 0.50 OR at least 75% of the results are in accordance with the hypotheses) AND correlation with related constructs is higher than with unrelated constructs
	?	Solely correlations determined with unrelated constructs
	-	Correlation with an instrument measuring the same construct < 0.50 OR $< 75\%$ of the results are in accordance with the hypotheses OR correlation with related constructs is lower than with unrelated constructs
Responsiveness		
Responsiveness	+	(Correlation with an instrument measuring the same construct ≥ 0.50 OR at least 75% of the results are in accordance with the hypotheses OR AUC ≥ 0.70) AND correlation with related constructs is higher than with unrelated constructs
	?	Solely correlations determined with unrelated constructs
	-	Correlation with an instrument measuring the same construct < 0.50 OR $< 75\%$ of the results are in accordance with the hypotheses OR AUC < 0.70 OR correlation with related constructs is lower than with unrelated constructs

MIC = minimal important change; SDC = smallest detectable change; LOA = limits of agreement; ICC = intraclass correlation coefficient; AUC = area under the curve

+ positive rating; ? indeterminate; - negative rating. Source Terwee et al¹⁸

Table 3. Summary of included studies

Measure	Study	Report	Age (y)	No. of Domains	No. of items	Recall period	Completion time (mins)	Study Population	Generic/Disease Specific	Country of origin
Child Health Questionnaire – Parent Form 50	Drotar ²¹ Ferro ²² McCullough ²³ Wake ²⁴	Parent	5-18	11 (physical functioning, role/social -physical, general health perceptions, bodily pain/discomfort, parental impact time, role/social-emotional/behavioural, self-esteem, mental health, general behavior, family activities, family cohesion, change in health)	50	4 weeks	Not reported	Chronic illness Epilepsy Cerebral palsy Cerebral palsy	Generic	USA
ConQol	Macran ²⁵	Self	8-11	3 (symptoms, activities, relationships)	29	1 week	Not reported	Congenital heart disease	Disease specific - congenital heart disease	UK
			12-16	4 (symptoms, activities, relationships, control and coping)	35					
CP-QOL	Waters ²⁶	Self	9-12	5 (social well-being and acceptance, functioning, participation and physical health, emotional well-being, pain and impact of disability)	52		15-25	Cerebral palsy	Disease specific – cerebral palsy	Australia
